

ABSTRACT

In an adaptive array terminal, at least one of two antennas (ANT#1, ANT#2) is a movable antenna. A display unit (~~6~~) of the terminal displays reception levels of, or level difference between, the two antennas. Thus, it becomes possible for a user to adjust an angle of the antenna such that reception levels of the two antennas come closer to the same level. Alternatively, control unit (~~8~~) of the terminal automatically adjusts the antenna angle so that reception level difference between the two antennas becomes not higher than a prescribed value.
